SOAP APIs

SOAP API support is included with all Control Center accounts, including trial accounts. This section provides an overview of the APIs, including the development process and coding standards.

For reference information about individual API functions, see the online API schema. If your user account has access to the APIs, you'll see your license key below. All users can view the API path information. (Do not modify the path in any way; make sure to use it as described in the documentation.)

License Key	Your account does not have access to the APIs

API Path	https://api3.jasperwireless.com

Customer Access. Be aware that the Knowledge Base doesn't display the API license key for users with customer roles. A customer must request the key from their enterprise.

Roles with Access

Service provider, account, and customer users can use the APIs. However, user access is limited by the following:

- **Access Type**. The user must have an Access Type of *API Only* or *Both API and UI* in order to access the APIs. You can find that information on the User Details page: Admin > Users > *User Name* link > Access Type.
- **Role**. If a user with UI access can perform the function within the Control Center web interface, then a user with the same role and API access will be able to complete the task via an API call. There is no single role that will guarantee access for all function calls. See the REST API/Role Matrix for a complete list of roles and the APIs they can use.

Typically, an enterprise will create user accounts with access to both the UI and the APIs for their engineering team during development. For auditing purposes, Cisco recommends that production code use a dedicated Control Center user whose sole purpose is to execute API functions. When you create

the user, you can specify that the user has API-only access to Control Center. See Creating Users for details.

Field Restrictions. While multiple roles may have access to the same API, not every role will have access to all the fields listed in the documentation. You can verify field access for a particular role by logging into the web interface as a user with the same role who also has web interface access and then looking for the field.

AccountAPIOnly Role. This legacy role has access to Control Center through the API, but not through the web interface. The purpose of this role was to provide restricted access to Control Center for service provider partners using a different platform. We recommend that current users take advantage of the Access Type attribute to create users with API-only access to Control Center rather than creating users with the AccountAPIOnly role.

***IP Address Restrictions* (ADD-ON).** If an enterprise implements IP Address Restrictions, an API user might not have API access if their IP address falls within a restricted range.

Single Sign-On Restriction. APIs are not available to users who access Control Center using the Single Sign-On (SSO) authentication process. SSO users are UI-only users by default. See Network Single Sign-On for details.

Terminology

Terminals. Many API functions refer to a device as a “terminal.” The terms are interchangeable.

Network Access Config. This is a legacy Control Center term for a communication plan. We continue to use the term because several long-standing APIs use the term in their function names.

For information about other terms, refer to the Glossary.
